

Data Transformation with data.table :: CHEAT SHEET

Basics

data.table is an extremely fast and memory efficient package for transforming data in R. It works by converting R's native data frame objects into data.tables with new and enhanced functionality. The basics of working with data.tables are:

dt[i, j, by]

Take data.table **dt**,
subset rows using **i**
and manipulate columns with **j**,
grouped according to **by**.

data.tables are also data frames – functions that work with data frames therefore also work with data.tables.

Create a data.table

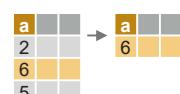

data.table(a = c(1, 2), b = c("a", "b")) – create a data.table from scratch. Analogous to `data.frame()`.

setDT(df)* or as.data.table(df) – convert a data frame or a list to a data.table.

Subset rows using i

dt[1:2,] – subset rows based on row numbers.

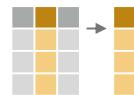

dt[a > 5,] – subset rows based on values in one or more columns.

LOGICAL OPERATORS TO USE IN i

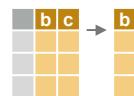

| | | | | | |
|---|----|----------|------|---|-----------|
| < | <= | is.na() | %in% | | %like% |
| > | >= | !is.na() | ! | & | %between% |

Manipulate columns with j

EXTRACT

dt[, c(2)] – extract columns by number. Prefix column numbers with “-” to drop.

dt[, .(b, c)] – extract columns by name.

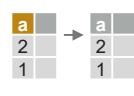

dt[, .(x = sum(a))] – create a data.table with new columns based on the summarized values of rows.

Summary functions like `mean()`, `median()`, `min()`, `max()`, etc. can be used to summarize rows.

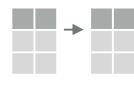

COMPUTE COLUMNS*

dt[, c := 1 + 2] – compute a column based on an expression.

dt[a == 1, c := 1 + 2] – compute a column based on an expression but only for a subset of rows.

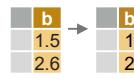

dt[, `:=` (c = 1, d = 2)] – compute multiple columns based on separate expressions.

DELETE COLUMN

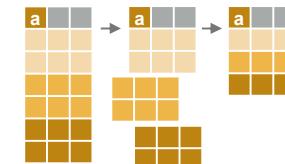

dt[, c := NULL] – delete a column.

CONVERT COLUMN TYPE

dt[, b := as.integer(b)] – convert the type of a column using `as.integer()`, `as.numeric()`, `as.character()`, `as.Date()`, etc..

Group according to by

dt[, j, by = .(a)] – group rows by values in specified columns.

dt[, j, keyby = .(a)] – group and simultaneously sort rows by values in specified columns.

COMMON GROUPED OPERATIONS

dt[, .(c = sum(b)), by = a] – summarize rows within groups.

dt[, c := sum(b), by = a] – create a new column and compute rows within groups.

dt[, .SD[1], by = a] – extract first row of groups.

dt[, .SD[N], by = a] – extract last row of groups.

Chaining

dt[...][...] – perform a sequence of data.table operations by chaining multiple “[]”.

Functions for data.tables

REORDER

setorder(dt, a, -b) – reorder a data.table according to specified columns. Prefix column names with “-” for descending order.

* SET FUNCTIONS AND :=

data.table's functions prefixed with “set” and the operator “:=” work without “-<” to alter data without making copies in memory. E.g., the more efficient “`setDT(df)`” is analogous to “`df <- as.data.table(df)`”.

Apply function to cols.

APPLY A FUNCTION TO MULTIPLE COLUMNS

| | | |
|-----|---|-----|
| a b | → | a b |
| 1 2 | | 1 2 |
| 2 2 | | 2 2 |

`dt[, lapply(.SD, mean), .SDcols = c("a", "b")]` – apply a function – e.g. `mean()`, `as.character()`, `which.max()` – to columns specified in `.SDcols` with `lapply()` and the `.SD` symbol. Also works with groups.

| | | |
|-----|---|-------|
| a b | → | a a m |
| 1 4 | | 1 1 2 |
| 2 5 | | 2 2 2 |
| 3 6 | | 3 2 2 |

`cols <- c("a")`
`dt[, paste0(cols, "_m") := lapply(.SD, mean), .SDcols = cols]` – apply a function to specified columns and assign the result with suffixed variable names to the original data.

Reshape a data.table

RESHAPE TO WIDE FORMAT

| | | |
|----------|---|--------------------|
| id y a b | → | id a x a z b x b z |
| A x 1 3 | | A 1 2 3 4 |
| A x 1 3 | | B 1 2 3 4 |
| B z 2 4 | | |
| B z 2 4 | | |

`dcast(dt, id ~ y, value.var = c("a", "b"))`

Reshape a data.table from long to wide format.

`dt` A data.table.
`id ~ y` Formula with a LHS: ID columns containing IDs for multiple entries. And a RHS: columns with values to spread in column headers.
`value.var` Columns containing values to fill into cells.

RESHAPE TO LONG FORMAT

| | | |
|--------------------|---|----------|
| id a x a z b x b z | → | id y a b |
| A 1 2 3 4 | | A x 1 3 |
| B 1 2 3 4 | | B x 1 3 |
| | | A z 2 4 |
| | | B z 2 4 |

`melt(dt, measure.vars = measure (value.name, y, sep = " "))`

Reshape a data.table from wide to long format.

`dt` A data.table.
`measure.vars` Columns containing values to fill into cells, often using `measure()` or patterns `(.)`.
`id.vars` Character vector of ID column names (optional).
`variable.name,`
`value.name` Names for output columns (optional).

`measure(out_name1, out_name2, sep = "_", pattern = "[ab]_(.*_)")`
`sep`(separator) or `pattern` (regular expression) are used to specify columns to melt, and parse input column names.
`out_name1, out_name2`: names for output columns (creates single value column), or `value.name` (creates a value column for each unique part of the melted column name).

Sequential rows

ROW IDS

| | | |
|-----|---|-------|
| a b | → | a b c |
| 1 a | | 1 a 1 |
| 2 a | | 2 a 2 |
| 3 b | | 3 b 1 |

`dt[, c := 1:N, by = b]` – within groups, compute a column with sequential row IDs.

LAG & LEAD

| | | |
|-----|---|--------|
| a b | → | a b c |
| 1 a | | 1 a NA |
| 2 a | | 2 a 1 |
| 3 b | | 3 b NA |
| 4 b | | 4 b 3 |
| 5 b | | 5 b 4 |

`dt[, c := shift(a, 1), by = b]` – within groups, duplicate a column with rows lagged by specified amount.

`dt[, c := shift(a, 1, type = "lead"), by = b]` – within groups, duplicate a column with rows leading by specified amount.

read & write files

IMPORT

`fread("file.csv")` – read data from a flat file such as `.csv` or `.tsv` into R.

`fread("file.csv", select = c("a", "b"))` – read specified columns from a flat file into R.

EXPORT

`fwrite(dt, "file.csv")` – write data to a flat file from R.
